

Problem A. Strange Device

Time limit: 4 seconds
Memory limit: 512 megabytes

Archaeologists have found a strange device that was probably created by some ancient civilization. The device has a screen that displays two integers: x and y .

After exploring the device the scientists have made a conclusion that the device is kind of a clock. It measures time t passed from some moment in the past, but shows it in some weird way, probably used by the creators of the device. If the time passed is an integer t , the two integers displayed are: $x = ((t + \lfloor \frac{t}{B} \rfloor) \bmod A)$, and $y = (t \bmod B)$. Here $\lfloor x \rfloor$ is the *floor function* — the greatest integer less or equal to x .

The archaeologists have studied the device and found out that its screen wasn't turned on all the time. Actually it was only working during n continuous periods of time, the i -th of them was from the moment l_i to the moment r_i , inclusive. Now the scientists would like to calculate how many distinct pairs (x, y) were shown by the device when its screen was on.

Two pairs (x_1, y_1) and (x_2, y_2) are distinct if $x_1 \neq x_2$ or $y_1 \neq y_2$.

Input

The first line contains three integers n , A , and B ($1 \leq n \leq 10^6$; $1 \leq A, B \leq 10^{18}$).

Each of the following n lines contains two integers l_i and r_i , the beginning and the end of the i -th segment $[l_i, r_i]$ when the device screen was turned on ($0 \leq l_i \leq r_i \leq 10^{18}$; $r_i < l_{i+1}$).

Output

Output the number of distinct pairs (x, y) that were shown on the device screen when it was turned on.

Scoring

Let $S = \sum_{i=1}^n (r_i - l_i + 1)$ and $L = \max_{i=1}^n (r_i - l_i + 1)$.

Subtask 1 (points: 10)

$S \leq 10^6$.

Subtask 2 (points: 5)

$n = 1$.

Subtask 3 (points: 5)

$A \cdot B \leq 10^6$.

Subtask 4 (points: 5)

$B = 1$.

Subtask 5 (points: 5)

$B \leq 3$.

Subtask 6 (points: 20)

$B \leq 10^6$.

Subtask 7 (points: 20)

$L \leq B$.

Subtask 8 (points: 30)

No additional constraint.

Examples

input	output
3 3 3 4 4 7 9 17 18	4
3 5 10 1 20 50 68 89 98	31
2 16 13 2 5 18 18	5

Note

In the first test, the device screen shows the following integers.

t	(x, y)
4	(2, 1)
7	(0, 1)
8	(1, 2)
9	(0, 0)
17	(1, 2)
18	(0, 0)

So there are four distinct pairs $(0, 0)$, $(0, 1)$, $(1, 2)$, $(2, 1)$.
